Actually -- and this is slightly embarrassing -- at the time that I wrote the last post, I had only verified that the fieldarray would contain the primary key that I needed (to set the upload directory), and I had not attempted to upload the file into that directory.

As it turns out, when you submit an uploaded file, `_cm_initialiseFileUpload()` will be called a second time -- and the fieldarray will be empty. I ended up having to do the above hack for both the upload and picker transactions in order to make them work as I intended.

So, to answer your question, I definitely would feel more comfortable if this data was provided directly (vs my workaround), but it would be your call on how best to do it. Having an argument called "fieldarray" might be misleading, as it would need to access the fieldarray from the previous transaction. I'm not sure what the implications are here, but it almost seems like there could be separate functions that get called, one initialization for entering the file upload and one for leaving it with the submitted file.
