I can immediately see that you are doing some things in a questionable way.

1) When using RDCsingleton:getInstance('table.class.inc') you do not need to require/include the class file beforehand as this is handled automatically in the getInstance method.

2) The ability to access classes in another subsystem should be handled by putting the path to that other subsystem in the htaccess file. Alternatively you can use 'subsystem/table.class.inc' in the call to getInstance() as this will automatically update include_path.

3) I do not understand why in the _cm_pre_getData method for that table you are reading data from a different table in a different subsystem. Your LIST1 task should go directly to the child table without having to go through the parent table.
