Hi,

I'm accessing some existing PostgreSQL databases on macos. Most of these have a primary key "id" whereas the foreign key is usually object\_id; I know that it is preferred using the same name, but that's no option. Luckily include.library.inc contains a function convert\_parent\_id\_to\_child\_id() to handle this particular case.

The function is called in std.table.class.inc, in the getData() function (line 2551 in the last version).

However for this to work properly the call to where2array(\$where, \$this->pageno, false) a few lines higher should be called with the last parameter set to true.

Regards,

Patrick
