Subject: How to deal with Implicit-Or Split limitations

To illustrate a workflow requirement I am struggling with, let's look at the workflow as described in http://www.tonymarston.net/php-mysql/workflow.html#sample:

As an example, if for whatever reasons a new business requirement is: Allow order cancellations by customers anytime after charging credit card but before shipment (and of course refund payments minus a handling fee as part of the order cancellation procedure). This requirement could be modeled in a straight forward manner like this:

However, such workflow would require multiple Implicit-Or splits without any timed transitions as currently required in Radicore. So, how should one go about thinking, modeling and implementing such a business requirement in Radicore workflow?

As an implicit OR split can only have 2 outbound arcs you will have to introduce another place after D which effectively says "Cancel or Continue". So as soon as the Shipment (Continue) tales place the Cancel operation then becomes disabled.

Note that an implicit OR split can only have two arcs, and one of the transitions MUST have a timer as a trigger. If you want more than one arc, or conditions without a timer, then you MUST use an explicit OR split.

Not sure I grasp this completely, so based on what I understand here are 2 solutions that approximate the required behavior.

Solution 1:

Solution 2:

Out of these 2, I think that the second solution is closer to the required behavior.
Any other solutions to get even closer to the business requirement?

Your requirement is that at the shipping stage there should be a choice - either ship or cancel.
When one of these choices is made it disables the other. You must build this choice into your
workflow using an Explicit OR split.

Yes, I think I did that in both solutions. In solution 1 I added an Explicit-Or to allow choice between
cancel or continue before the "Ship" transition. In solution 2, I made all the transitions between
"credit card charge" and "ship" into Explicit-Or with a 'cancel' arc, so that order could be canceled
at any stage. Am I missing something?

The more I read this post the more I realise that what you are trying to do is perfectly logical, yet
my implementation does not allow it. I have gone back to my original reference material at
http://martinfowler.workflowpatterns.com/documentation/docum ents/vanderaalst98application.pdf
and I now see that my implementation is too restrictive. I shall start work on modifying it so that an
Implicit-OR-split can have more than 2 arcs, and that it need not have a transition with a TIMER
trigger. I will post the updated code here as soon as I can.

Actually, after reviewing the source code of the workflow engine, I think it already supports implicit-or splits with multiple arcs without requirement for having one timed transition following it.

You just have to remove this constraint from wf_workflow_s01.class.inc, function _cm_validateUpdate:

```
            if ($arc['arc_count'] > 2) {
                // "Too many arcs of type 'OR-split (Implicit)' at place '$place_name'"
                $errors[] = getLanguageText('e0065', $place_name);
            } // if
```

BTW, that paper in your link is written by the same professor Wil van der Aalst who built the website that I linked here http:// radicore.org/fud/index.php?t=msg&th=891&goto=5940&#msg_5940.

It's a little more complicated than that. Attached is a zip file which contains the changed scripts. Let me know if it works.
