Subject: Access non key data from parent table

I am trying to use the ADD4 transaction from a LIST2 transaction to add multiple rows of data to a table based on a parent record selected. However, to build the select clause for the data I want to add I need to know the value of a field from the selected parent row that is not a key. I understand that only the key fields are passed in context to the ADD4 (child) transaction.

How can I either pass the non-key data to the child ADD4 transaction or access the parent table to retrieve it from the child transaction?

Thanks

Graham
