OK. $where and $selection now show expected results:

1. Without making selections $where and $selection both hold the primary key
2. With selections $where holds the orimary key and $selection holds the selections made

However, if I make selections and then set $selection = $where in _cm_initialise (to match scenario 1) I still get the error message 'Primary key (primary_key_id) is not complete - check selection'.

Do I need to do something more complex than simply setting $selection?

A solution I can use if the approach I was taking is not valid is to trap that selections have been made and display a custom error telling the user not to make selections. This works OK.
