Hi Tony,

did you somewhere describe or is there an example how to categorize a child record to more than one parent entry?

I have a parent child relationship where I would like to create child relationships with more than one parent. This would be a n:m relationship. The cild record should be shown each time one of the parent records are chosen.

What would be the best solution to do this? With a n:m transaction pattern? Or would it be better to create a field in the child database where all the parent keys are stored?
