It is not standard practice to have an entire website accessed through HTTPS. It is normal to use HTTP for everything except those pages which *must* be secured, in which case HTTPS is used. Radicore follows this convention by assuming everything is HTTP *unless* it has to be HTTPS. A website is either HTTP only or mostly HTTP with some HTTPS.

Instead of trying to install and evaluate this software on a remote server over which you obviously have no control, why don't you do what everyone else does and install it on your own local PC? This would be the best way to develop, test and debug any applications you intend to write.

I do not understand why deleting and recreating the AUDIT database would cause a login error. This is only caused when the user_id/password entered on the screen does not match what is in the USER table. The AUDIT database is not accessed until *after* the logon credentials have been successfully validated.
