If you look at the contents of _cm_output_multi() you will see a switch statement like the following:

```
$outarray = array();

switch ($name) {
    case 'multi1':
        // return a non-empty array to print an empty line
        $outarray[] = array('dummy' => '');
        break;

    case 'multi2':
        // return a non-empty array to print an empty line
        $outarray[] = array('dummy' => '');
        break;

    case 'multi3':
        // return a non-empty array to print an empty line
        $outarray[] = array('dummy' => '');
        break;

    case 'multi4':
        // return a non-empty array to print an empty line
        $outarray[] = array('dummy' => '');
        break;

    .....

    default:
        // return a non-empty array to print an empty line
        $outarray[] = array('dummy' => '');
        break;
} // switch

return $outarray;
```

Each time this method is called is has a different 'multiN' value in $name, so within the relevant 'case' statement you require code to construct $outarray before it is returned. You are currently outputting both a label and a text field for each line, so in the situation where the text field is empty and you do not want the line printed at all then do nothing as $outarray is already empty. If you put ANYTHING at all in $outarray then the line WILL be printed even if there are no values to print.
